Assessing the Prevalence of Intestinal Parasitic Infections (IPIs) Among the Children of Geidam Central Primary Yobe State, Nigeria.

ABSTRACT

Background: Intestinal parasitic infections (IPIs) is one of the preventable and avoidable public health problems that affect a significant portion of school-aged children and cause a lot of predominant physical and intellectual health challenges. Despite their significant public health importance, they remain largely neglected by the government, medical community, and international health organizations. This neglect occurs due to several factors such as the most affected people belonging to the poorest and less privileged communities who often live in remote rural areas or urban slums with little political voice and coupled with the nature of the infection as they are not highly visible and do not cause explosive outbreaks that attract public attention to take necessary measures.

Aims: This research study is aimed at assessing the prevalence of intestinal parasitic infections (IPIs) among the children of Geidam Central primary school Yobe state, Nigeria.

Study Design: A cross-sectional research method was used.

Place and Duration of Study: Laboratory department, Yobe State Specialist Hospital (YSSH) Geidam, and the study was conducted within months.

Methodology: A total number of 36 stool specimens were collected from primary 1-6 children, and six (6) children were randomly selected from each class, totaling 36 stools of 36 children. The stool samples were taken to YSSH, Geidam for microscopic examination to ascertain the presence of IPIs cysts, larva, or ova. The data were analyzed using frequency and percentage with the aid of the statistical package for Social Sciences (SPSS) version 20 statistical software and presented in tables and figures.

Results: Out of the 36 children that were examined for the prevalence of an intestinal parasitic infections (IPIs), 19 (52.65%) were infected with different intestinal parasitic infections (IPIs) identified and these IPIs were Ascaris lumbricoides with total percentage of 16.63%, Hookworm with total percentage of 13.86%, Giardia with total percentage of 5.54%, Strongyloides stercoralis with total percentage of 8.31%, Trichuris trichiura with total percentage of 5.54% and Enterobius vermicularis with total percentage of 2.77%.

Out of the 36 children, 19 (52.65%) were infected with different IPIs. Ascaris lumbricoides showed the highest rate of infection (16.63%), followed by Hookworm, Giardia, Strongyloides stercoralis, Trichuris trichiura, and Enterobius vermicularis (13.86%, 5.54%, 8.31%, 5.54%, and 2.77% respectively).

Conclusions: This research study established that there is a prevalence of IPIs among children of Geidam central primary school. This may have a connection with different potential risk factors such as walking barefoot, poor hand-washing habit, open defecation, absence of proper latrine utilization, etc. Therefore, the government should put more efforts into reducing children's morbidity and mortality associated with IPIs through health education at the primary schools' level and the development of community awareness campaigns in order to improve environmental sanitation and personal hygiene, as well as free deworming programs, these three intervention tailored to suit prevention, control and chemotherapy measures towards curtailing IPIs.

Keywords: Assessing, prevalence of IPIs, Children, Central Primary School, Geidam Yobe State, Nigeria.
1. **INTRODUCTION**

Intestinal Parasitic Infections (IPIs) are one of the most common diseases in Nigeria, especially among children of school-aged and IPIs is positively associated with demographic factors. The World Health Organization (WHO) has recognized intestinal parasitic infections (IPIs) as one of the neglected tropical diseases (NTDs) as it is ubiquitous and persistently associated with low educational levels, malnourishment, and the nature of the infection as they are not highly visible and do not cause explosive outbreaks that attract public and media attention to take necessary measures. Despite their significant public health importance, they remain largely neglected by the government, medical community, and international health organizations (1). This neglect occurs due to several factors such as the most affected people belong to the poorest and disadvantaged communities who often live in remote rural areas or urban slums with little political voice and coupled with the nature of the infection as they are not highly visible and do not cause explosive outbreaks that attract public and media attention to take necessary measures (2,3).

### 1.1 Global Prevalence of Intestinal Parasitic Infections (IPIs) and its Associated Risk Factors

The World Health Organization (WHO) has recognized that soil-transmitted helminths (STHs) are causing intestinal parasitic infections (IPIs) and related it as one of the neglected tropical diseases (NTDs) as it is ubiquitous and persistently associated with low educational levels, malnourishment, and the nature of the infection as they are not highly visible and do not cause explosive outbreaks that attract public and media attention to take necessary measures. The high prevalence of IPIs is attributed primarily to lower educational levels, which are associated with inadequate knowledge and awareness regarding infection transmission and prevention, as well as limited access to safe drinking water, inadequate personal hygiene, poor environmental sanitation, and the widespread food contamination (10, 10). The risk factors of IPI have extensively been discussed by von Huth, Kofoed (3), Terefe, Ross (12), and Forson, Arthur (11), and hence will not be elaborated in detail in this review. Briefly, demographic factors are closely associated with the high prevalence rate of IPIs (13). For examples, having large household members and having inadequate knowledge of health awareness are positively associated with intestinal parasitic infections (IPIs) (3, 14). Large households are known to have more than seven members in a house, and this may increase the risk of IPIs due to over-crowdedness (14, 15). The lack of sanitation and health care knowledge increases their risk of disease transmission as most of them may not be aware of the key sources and communal behaviors that exacerbate infection prevalence among the population (3, 16). Communities who prefer to stay in close proximity to rivers as their water source for daily chores including bathing, washing, and consumption of untreated water may expose the community to contaminated water harboring different species of protozoa parasites (17, 18). Furthermore, due to the lack of functioning toilets in most homes, a single pit latrine consisting of a pit that is...
Diseases associated with Intestinal parasitic infections (IPIs)

Diseases associated with T. trichiura, A. lumbricoides, A. duodenale and N. americanus. T. trichiura, A. lumbricoides, A. duodenale, and N. americanus are trichuriasis, ascariasis, ancylostomiasis, and necatoriasis, respectively. Anemia and malnutrition are two intertwined diseases that are strongly associated with IPI (23-27). STHs in specific, play a role in inducing intestinal bleeding and red blood cell destruction, leading to anemia (24, 26, 28). Specifically, co-infection of T. trichiura, T. trichiura and hookworm may have synergistic effects on causing blood loss, impairing re-absorption, and ingesting iron (28, 29). As STHs have designed appendages to attach to the host intestinal mucosa, impaired digestion and poor absorption of nutrients may occur in the infected individual with damaged gut epithelium, consequently leading to malnutrition (25, 28, 30). Malnutrition may then lead to underweight as well as stunted growth and development (27, 28). Rajoo et al. (2017) stated that the high prevalence rate of stunting (31.7%) is found among rural children infected with STHs in Malaysia, followed by a prevalence rate of 28.6% among those being underweight. STHs-causing IPIs may also lead to intestinal epithelial damage as these STHs can attach to the gut mucosa and disrupt the intestinal barrier, subsequently destroying the cell cytoskeleton and resulting in cell damage (31). This is often accompanied by intestinal inflammation as cell damage may enhance the intestinal infiltration of activated neutrophils (32). This is supported by a study conducted by Garzón et al. (2017) which showed that the production of fecal S100A12, a protein that regulates inflammatory responses and neutrophil infiltration, was upregulated in IPIs-infected individuals, implying an association between intestinal inflammation and intestinal parasitic infections (IPIs). Diarrheas, amoebiasis, and cryptosporidiosis are common diseases caused by G. lamblia, E. histolytica, and Cryptosporidium spp., respectively (33). Individuals infected with E. histolytica may develop clinical symptoms such as dehydration, dysentery, and acute diarrhea (34). However, having been infected with G. lamblia will lead to abdominal cramping, bloating, and diarrhea among the populations (35). Healthy individuals who are infected with Cryptosporidium spp. may have self-limiting diarrhea, but cryptosporidiosis may contribute to chronic diarrhea in immunocompromised individuals (33). As diarrhea and dysentery are common among the individuals infected with intestinal protozoa, weight loss and malnutrition can be observed among the communities (36). Persistent diarrhea may result in increased loss of fluids and electrolytes, leading to weight loss and malabsorption of nutrients such as carbohydrates, protein, and fats, resulting in malnutrition (37). Reinfection of STHs may occur when there are no improvements in terms of environmental cleanliness and personal hygiene among the communities. STH prevalence often rebounds to the pre-treatment levels in a relatively short time frame of 6 to 12 months (38, 39). This showed that the complete elimination of parasites cannot be achieved by relying solely on anti-helminthic treatments. Speich et al. (2016) reported that the reinfection rate in Tanzania for T. trichiura was 37.2% (42/113 treated children) after 18 weeks followed by treatment with anti-helminthic drugs. Furthermore, 57 of 165 (34.6%) children were found to be reinfected with A. lumbricoides, and 18 of 72 (25.0%) children were reinfected with hookworms. Sanitation and personal hygiene may reduce the re-introduction of parasitic...
agents into the local environment, particularly by actively infected individuals, where such methods will be further reviewed in the following section. Therefore, anti-helminthic drugs should be administrated alongside with sufficient awareness on of the importance of hygienic practices in the susceptible community. Improved environmental [54]. In view of the above, because of the above, stated IPIs burdens was the reason behind this research study was conceived and aimed at assessing the prevalence of Intestinal parasitic infections (IPIs) among the children of Central Primary School Geidam, Yobe state Nigeria.

2. MATERIALS AND METHODS

A specimen container, hand gloves, and facemasks were used while collecting the stool specimen and the selected children were guided on how to use hand glove, facemasks and how to defecate defecate and insert some portion of the stool in to sample bottle without spoiling the sample bottle and the samples collected were taken to Yobe state specialist hospital (YSSH) Geidam for microscopic examination of the stool specimens to ascertain the presence of IPIs cysts larva or ova. A cross-sectional research method was used, a total number of 36 stool specimens were collected from primary 1-6 children; and six (6) children were randomly selected from each class totaling 36 children and the data was analyzed using percentage with the aid of statistical package for Social Sciences (SPSS) version 20 statistical software and presented in tables and figures.

2.1 Aims: This research study is aimed at assessing the prevalence of intestinal parasitic infections (IPIs) among children of Geidam Central primary school Yobe state, Nigeria.

2.2 Objectives: This is to sensitize school-aged children about the causes and risk factors of Intestinal parasitic infections (IPIs) through health education at the school level and to develop general public awareness campaigns. The policymakers can utilize the findings of the research in making necessary actions towards eliminating Intestinal parasitic infections (IPIs) through providing health education programs at the primary school level and free anthelminthic drugs policy for all school-aged children.

2.3 Study Area: The study was conducted in Geidam local Government area of Yobe state Nigeria at the Central primary school Geidam.

2.4 Study population: The study population was children of Geidam central Primary school which comprised all classes ranging from class 1 to 6 and both genders were equally selected, i.e. three males and three females from each class totaling 36 children.

3. RESULTS AND DISCUSSION

3.1 Results

Out of the 36 children that were examined for the prevalence of Intestinal parasitic infections (IPIs) in Geidam central primary school, 19 (52.65%) children were infected with different sorts of intestinal parasitic infections (IPIs). These intestinal parasitic infections (IPIs) identified were included Ascaris lumbricoides with total percentage of 16.66%, Hookworm with total percentage of 13.86%, Giardia with total percentage of 5.54%, Strongyloides stercoralis with total percentage of 8.31%, Trichuris trichiura with total percentage of 5.54%, Enterobius vermicularis with total percentage of 2.77%. The identified IPIs in the present study were A. lumbricoides, Hookworm, Giardia, S. stercoralis, T. trichiura, and Enterobius vermicularis (16.63%, 13.86%, 5.54%, 8.31%, 5.54%, and 2.77% respectively). Among the 36 selected children, males maintain a high prevalence of intestinal parasitic infections (IPIs) with a total percentage of 36.11% and females hold a lower rate with total percentage of infection (16.66%) and among. Regarding the age group, children with 10-12 years (class 4-6) have shown a high rate prevalence with total (33.33%) while their counterpart counterparts of 6-9 years hold a lower prevalence with total percentage of 19.44% respectively. And among Concerning the different classes, class 1 has 5.5%, class 2 has 8.33%, class 3 also has 5.55%, as well as class 4 has 11.11%, class 5 has 13.88% and class 6 has 8.33% respectively in
contrast higher rates were detected in class 4, class 5 and class 6 (13.88%, 11.11%, and 8.33% respectively). In this result of all an Intestinal parasitic infections (IPIs) burdens. Ascaris Ascaris has high prevalence with total percentage of (16.63%) and Hookworm with total percentage of (13.86%) and the other three with average prevalence while Enterobius vermicularis maintain a lower prevalence with total percentage of (2.77%). According to gender result males have high prevalence (36.11%) than females (16.66%), as well as according to age group result children with 10-12 years have high prevalence (33.33%) than children with age 6-9 years (19.44%) and according to the class groups result children of class 5 (13.88%) and class 4 (11.11%) holds highest prevalence than the other classes, whereas class 3 (8.33%) and class 6 (8.33%) maintain average prevalence and then class 1 (5.55%) and class 3 (5.55%) have lowest prevalence respectively. (see below table and figures for more details).

Table1: Shows Prevalence of Intestinal Parasitic Infections (IPIs) among 36 selected children, prevalence in Gender, prevalence in Age group, and prevalence I different classes.

4. CONCLUSIONS

This research study established that the prevalence of Intestinal parasitic infections (IPIs) among children of Geidam central primary school Geidam. The prevalence is higher in males than in females and the older children than the younger ones. This may have a connection that the older males have higher exposure to different potential risk factors such as walking barefoot, poor hand washing habits, open defecation, and absence of proper latrine utilization are the major determinant factors for the high prevalence of hookworm infection. Therefore, the government should put more efforts effort to reduce children’s morbidity and mortality associated with IPIs through health education at the primary schools’ level and the development of community awareness campaigns in order to improve environmental sanitation and personal hygiene, as well as free deworming programmes and these three interventions tailored to suit prevention, control and chemotherapy measures of IPIs.

RECOMMENDATIONS

The Intestinal Parasitic Infections (IPIs) can be controlled and prevented through three main intervention strategies for controlling and preventing of IPIs, namely: anthelminthic drug treatment, improved sanitation, and health education.

(i). Deworming: Deworming can significantly reduce the number of adult worms in the gastrointestinal tract which is also reflected in reduced egg counts. The World Health Organization (WHO) recommends both albendazole and mebendazole as the drug of choice to be used in the public health program for controlling and preventing of IPIs.

(ii). Sanitation: Improvement of sanitation that is intended at controlling transmission by reducing soil and water contamination is another way for IPIs interventions. Sanitation is the only definitive intervention to control IPIs. In order for this intervention to be fully effective, it should cover a high percentage of the population at a broad scale.

Figure. 4. Shows prevalence of IPIs Among Different Age Groups
(iii) Health Education: Health education at schools the school level and general public awareness campaign programme program is another major intervention in controlling IPIs aimed at reducing transmission and re-infections by promoting healthy behaviours such as encouraging the use of latrines, wearing shoes, and hygienic behaviours. Without a change in sanitary behaviours, regular deworming cannot achieve a significant reduction in IPIs transmission. In addition, health education can be offered simply and economically by decreasing cost, increasing levels of knowledge, and decreasing re-infection rate. Likewise, it does not involve any contraindications or risks. Its benefit goes beyond the control of IPIs infections as it can build trust and engage communities, which are essential aspects of the success of public health initiatives. Children should be strictly warned about walking barefoot in areas where hookworm is common and where there may be human faecal contamination of the soil.

ETHICAL APPROVAL
A letter dated 10th October 2019 was written to the Yobe State Ministry of Health with a detailed explanation of the research aims & objectives seeking ethical clearance to conduct this research study through the Director of research and the Yobe State Ethical Committee (YOHREC) executed a meeting on my research proposal and then clearance letter was issued to me dated, 15th October 2019 with Ref. No: MOH/GEN/747/VOL.II. However, the research was not conducted on time due to the insecurity of Boko Haram which necessitated the Geidam’s Community to flee the town, until this January 2022 when the insecurity situation subsided. That the clearance letter was presented to Headmaster Geidam Central primary school and he granted permission to collect the stool sample.

FUTURE PROSPECTS
Due to financial constraints, I would like to express a final thought on future prospects, which seem to me to be just as interesting to cover all parts of Geidam primary schools and Yobe state at large to ascertain the exact prevalence of intestinal parasitic infections (IPIs) in the case study area, as 1 primary school is too limited to achieve our desired aims and objectives and therefore suggested for other researchers to utilize this opportunity to cover the whole state.
