Challenges in the Management of Childhood Cancer Patients in a Tertiary Hospital in Southern Nigeria

ABSTRACT

Introduction: The burden of childhood cancer is an important child health concern globally. Several million new cases are diagnosed annually, but the greatest burden is borne by developing countries. The management of paediatric cancer patients in these settings is fraught with several challenges, which can significantly affect outcome.

Aim: To identify the various challenges in management of children with cancers in the University of Uyo Teaching Hospital Uyo, Nigeria and proffer interventions which may impact positively on their long term survival and quality of life.

Methods: A three year retrospective study of children admitted with cancers was carried out at the Haematology-Oncology unit of the department of Paediatrics, University of Uyo Teaching Hospital, Uyo Nigeria, from January 2019 and December 2021. The available records of their admission, treatment process, progress and outcome were reviewed.

Results: Of the thirty-eight (38) patients seen, all presented at a late stage of disease. The socioeconomic class of parents were mostly low (81.6%) and all treatments were self-sponsored, with 44.7% discharging against medical advice due to financial constraints.

Conclusion: The challenges in the management of paediatric cancer patients included late presentation, late diagnosis, financial constraints/poverty, burn-out of caregivers, with a resultant high frequency of discharge against medical advice. Greater awareness about childhood cancers, increased advocacy for governmental input by way of resources, infrastructure and health insurance policies would improve outcome.

Keywords: Cancers; challenges; children; Nigeria.

1. INTRODUCTION

Cancer, which is a notable cause of death in children, still has a high burden in most developing countries. It is an important child health concern globally. Childhood cancers account for an estimated 60 - 80% of the total burden of all new cancer cases worldwide [1,2].

Many children with cancers in low-income countries still die without access to proper therapy, and the overall 5-year survival is considerably poor in most sub-Saharan African countries [3-5].

Challenges abound in the management of paediatric cancer patients, which can significantly affect outcome of treatment. While developed nations are bothered about increased survival and cure rates, development of improved therapies and achievement of better quality of life [6], most developing countries are grappling with poor data records, ignorance, poverty, increased patronage of traditional medicine vendors, lack of centres with specialized health workers and diagnostic facilities, expensive chemotherapeutic drugs and lack of support at the level of the community [1,4,7,8].

The aim of this study was to identify the various challenges in management of children with cancers in the University of Uyo Teaching Hospital, and proffer interventions which may impact positively on their survival and quality of life.

2. METHODS

A three year retrospective study of children admitted with cancers into the Paediatric Haematology-Oncology Unit of the University of Uyo Teaching Hospital, Uyo, Nigeria between January 2019 and December 2021 was carried out. The available records of their admission, treatment process, progress and outcome were reviewed. Socioeconomic class was determined according to Oyedeji’s classification [9].

3. RESULTS

Of the one thousand, six hundred and five (1,605) children admitted in the study period, those who were diagnosed with various cancers
were thirty-eight (38), constituting 2.37% of the total number. Fig. 1 shows the percentage distribution of patients. Of the thirty-eight (38) reviewed, male comprised 25 (65.79%) and female 13 (34.21%), with a male to female ratio of 1.9:1. The age range of the children is seen in Fig. 2. Just over half of the children who presented were less than ten years of age. The various cases of cancers seen in the patients reviewed over the study period is as presented in Fig. 3. All the patients presented at a late stage of disease with all treatments being self-sponsored (Table 1). The socio-economic class of parents were mostly low (81.6%) as seen in Table 2. There was a 44.7% rate of discharge against medical advice due to financial constraints [10-12].

4. DISCUSSION

The higher percentage of male childhood cancer patients presenting at this facility in the study period is a common trend that has also been noted in various studies from the western part of Africa to Egypt in North Africa [13,14,15]. The age range 1 to 4 years and children greater than 10 years were majority. The high frequency of embryonal tumours such as nephroblastoma and retinoblastoma documented in this centre during the study period could be one of the contributing reasons why children less than 5 years of age were among the most affected [16]. Some other studies had also noted a higher frequency of childhood cancers in this age group [17,18].

While the challenges in the management of childhood cancers are recognized worldwide, they would differ in perspective between the low and middle income countries (LMIC), and the high income ones. For instance, this study showed that all the patients with cancers during the period of review presented late, at stages 3 or 4 of the disease with few showing features of metastasis. This observation is similar to those noted in studies carried out in other parts of Nigeria [13,14,17,19] and Africa [15]. Factors associated with late presentation and diagnosis in this centre, were found to be multi-factorial amongst which majorly included patient-related causes. The socio-economic and literacy level of most care-givers was quite low as seen in this study. Thus the associated poor awareness and ignorance of care-givers about cancers in the paediatric population, resulted in non-recognition of the symptoms of serious illness early enough. Also contributory, were financial constraints/poverty which affected healthcare seeking behaviours of many families. Late presentation is known to have a negative effect on the prognosis of childhood cancers. Awareness of cancers in children should be increased to tackle this problem.

The healthcare system also played a role in delayed diagnosis of some cancers, in that facilities for immunohistochemistry of some specimens needed for confirmatory diagnosis, was unavailable in the study centre. There was therefore need, for some specimens to be sent to other referral centres. During the COVID 19 lockdown, it became increasingly difficult to send out and receive promptly, such histological samples needed to make prompt diagnosis and institute treatment. The burden of investigations and treatment was borne by parents of affected children. This led to financial burn-out of most caregivers, who were unable to cope with payments for required histological and laboratory investigations for the confirmation of cancer, as well as sustaining drug purchase even while undergoing chemotherapeutic cycles. Such was noted by other studies within the country, and the African region [15,17,18]. The availability and coverage of the health insurance in the country is still poor, so out of pocket payments for healthcare services remains the norm. Increasing and expansion of the health insurance coverage, and advocating for its increased uptake by state and local government including private companies will mitigate this challenge.

Discharge from care against medical advice due to various reasons was high, noting also the high rate following financial constraints and overall poverty, a trend noted by other researchers [17,18]. As seen in this study, most of the affected families were of the low socioeconomic class. Also worthy of note is that the study period reviewed, spanned through the greater part of the COVID-19 pandemic and lockdown period. This further worsened unemployment and slowed down business progression in trying to curb the spread of the disease [20,21]. Unfortunately, this also resulted in huge financial and economic hardship at the level of many families in most parts of the world, including Nigeria [20,21]. This seems to have further contributed to the observations seen in this study, as most caregivers could not sustain chemotherapeutic drug purchase and investigations needed to appraise treatment progress.

5. CONCLUSION

The challenges in the management of paediatric cancer patients included late presentation and diagnosis, financial constraints/poverty, burn-out of caregivers, with a resultant high rate of discharge against medical advice. Greater awareness about childhood cancers, increased advocacy for governmental input by way of resources, infrastructure and health insurance policies would improve outcome. There is also
need to drive the establishment of dedicated regional paediatric cancer centres.
